

## **Operator Precedence**

**Operator precedence** determines the order in which the operators in an expression are evaluated.

For eg -

int 
$$x = 3 * 4 - 1$$
;

In the above example, the value of x will be 11, not 9. This happens because the precedence of \* operator is higher than - operator. That is why the expression is evaluated as (3\*4) - 1 and not 3\*(4-1).

## **Operator Precedence Table**

Operators	Precedence		
postfix increment and decrement	++		
prefix increment and decrement, and unary	++ + - ~ 1		
multiplicative	*/%		
additive	+-		
shift	<< >> >>>		
relational	< > <= >= instanceof		
equality	== [=		
bitwise AND	&		
bitwise exclusive OR	^		
bitwise inclusive OR			
logical AND	8.8		
logical OR			
ternary	?:		
_assignment	= <del>  = *= /= %= &amp;= ^=   =</del>		

**Associativity of Operators** 

If an expression has two operators with similar precedence, the expression is evaluated according to its **associativity** (either left to right, or right to left).

Operators	Precedence	Associativity	
postfix increment and decrement	++	left to right	
prefix increment and decrement, and unary	++ + - ~!	right to left	
multiplicative	* / %	left to right	
additive	+ -	left to right	
shift	<< >>>>>	left to right	
relational	< > <= >= instanceof	left to right	
equality	== !=	left to right	
bitwise AND	&	left to right	
bitwise exclusive OR	٨	left to right	
bitwise inclusive OR		left to right	
logical AND	&&	left to right	
logical OR		left to right	
ternary	?:	right to left	
assignment	= += -= *= /= %= &= ^=  = <<= >>= >>>=	right to left	

**Note -** These notes are just for a quick glance. We don't have to memorize them all at once. Most of these rules are very logical and we have been following them in a lot of instances already.
